

Hyperbolic Equations

Examples:

- Wave equation: $\frac{1}{c^2} u_{tt} = \Delta u$ appears in acoustics, electromagnetics, seismics, ...
- Advection equation: $u_t + \underline{v} \cdot \nabla u = 0$ models transport of a material at a steady velocity \underline{v} .

Here we shall focus on 1D advection equation:

$$\begin{cases} u_t + a u_x = 0 & , \text{ where } a = \text{constant} \\ u(x, 0) = \eta(x) \end{cases}$$

Exact solution: $u(x, t) = \eta(x - at)$

check: $u(x, 0) = \eta(x)$

$$u_x(x, t) = \eta'(x - at)$$

$$u_t(x, t) = -a \eta'(x - at)$$

$a > 0$:

Solution is a "pulse" traveling at speed a . Sign of a gives direction of propagation.

$a < 0$

$|a|$ = distance traveled in one time unit.

First approach that comes to mind is to use the following approximations:

$$u_x(x,t) = \frac{u(x+h,t) - u(x-h,t)}{2h} + O(h^2)$$

= centered differences in space

$$u_t(x,t) = \frac{u(x,t+k) - u(x,t)}{k} + O(k)$$

= forward differences in time.

→ numerical scheme: (notation: $U_j^n \approx u(x_j, t_n)$)

$$\boxed{\frac{U_j^{n+1} - U_j^n}{k} = -\frac{a}{2h} (U_{j+1}^n - U_{j-1}^n)} \quad (*)$$

$$U_j^{n+1} = U_j^n - \frac{ak}{2h} (U_{j+1}^n - U_{j-1}^n)$$

This numerical scheme is not practical because of stability reasons. (as we shall see later)

Lax Friedrichs method

$$\boxed{U_j^{n+1} = \frac{1}{2} (U_{j-1}^n + U_{j+1}^n) - \frac{ak}{2h} (U_{j+1}^n - U_{j-1}^n)}$$

(like $(*)$ but with U_j^n replaced by spatial average $\frac{U_{j+1}^n + U_{j-1}^n}{2}$)

(L-F. method is not used much in practice because of accuracy)

(106)

L-F. is Lax-Richtmyer stable and convergent provided:

$$\boxed{\left| \frac{ak}{h} \right| \leq 1} \quad (\text{CFL})$$

This is a rather large time step compared to what we had for parabolic problems (where $k = O(h^2)$).

CFL = Courant, Friedrichs, Lewy condition

$$\Leftrightarrow \begin{array}{l} \text{distance traveled in a time step} \\ |ak| \end{array} < \begin{array}{l} \text{cell size} \\ h \end{array}$$

Another way of looking at this condition:

$$u_t = -a u_x$$

\Leftrightarrow solution changes in time $\frac{a}{h}$ times faster than in space

\Leftrightarrow temporal resolution (k) must be at least $\frac{a}{h}$ times smaller than spatial resolution (h)

To shed some light on this and other methods for hyperbolic equations, we look at:

Method of Lines

Consider the advection equation together w/ the following B.C.:

$$\begin{cases} u_t + a u_x = 0 \\ u(0, t) = g_0(t) \end{cases}$$

if $a > 0$: This is an "inflow" boundary condition

think of $g_0(t)$ as a 'stylus' writing on paper moving at velocity a in the indicated direction.

We use this B.C. rather than the initial condition (Cauchy problem) we started with because it is more adapted to bounded domains.

Note: if $a < 0$ then inflow B.C. needs to be at $x=1$ because the direction of propagation is reversed.

To study stability, we make a further simplification and assume we have periodic boundary conditions:

$$u(0, t) = u(1, t) \quad (\Leftrightarrow) \quad (\text{inflow at } x=0) = (\text{outflow at } x=1)$$

By the way the solution we obtain happens to be the same if we had assumed a Cauchy data (I.C. $u(x, 0) = \eta(x)$) periodic (with period 1).

Let $U(t) = \begin{bmatrix} U_1(t) \\ U_2(t) \\ \vdots \\ U_{m+1}(t) \end{bmatrix}$

where $U_j(t) \approx u(x_j, t)$
and we have kept only values of u
at nodes that are not determined by B.C.

Semi discretizing advection eq in space with centered finite differences we obtain the (linear) system of ODEs:

$$\begin{cases} U_j'(t) = -\frac{a}{2h} (U_{j+1}(t) - U_{j-1}(t)), & \text{for } j=2, \dots, m \\ U_1'(t) = -\frac{a}{2h} (U_2(t) - U_{m+1}(t)), & j=1 \\ U_{m+1}'(t) = -\frac{a}{2h} (U_1(t) - U_m(t)), & j=m+1 \end{cases}$$

or in system form:

$$U'(t) = A U(t)$$

where

$$A = -\frac{a}{2h} \begin{bmatrix} 0 & 1 & & & -1 \\ -1 & 0 & 1 & & \\ & -1 & 0 & 1 & \\ & & & \ddots & \ddots \\ 1 & & & & -1 & 0 \end{bmatrix} \in \mathbb{R}^{(m+1) \times (m+1)}$$

$A =$ skew symmetric matrix : $A^T = -A$

\Rightarrow all its eigenvalues are purely imaginary.

proof: is very similar to showing all eigenvalues of a symmetric matrix $A=A^T$ are real.

let $(\lambda, x) =$ eigenpair of A with $x^*x = 1$.

Here $x^* \equiv \overline{(x^T)}$.

$Ax = \lambda x \Rightarrow \boxed{x^*Ax = \lambda x^*x = \lambda}$

\Downarrow^*

$(Ax)^* = (\lambda x)^* \rightarrow x^*A^* = \bar{\lambda} x^* \Rightarrow x^*A^*x = \bar{\lambda} x^*x$

$\Rightarrow \boxed{-x^*Ax = \bar{\lambda}}$

therefore $\bar{\lambda} = -\lambda$ i.e. λ is imaginary.

$A =$ circulant matrix meaning a row can be obtained from previous one by a circular shift.

\Rightarrow eigenvectors of A (and of any circulant matrix) are

$$u_j^p = e^{2i\pi p j h}$$

, $p = 1, 2, \dots, m+1$
 $h = 1, 2, \dots, m+1$

and $\lambda_p(A) = \frac{-ia}{h} \sin(2\pi p h)$ (no need to remember!)

i.e. eigenvalues of A lie on interval $[-\frac{ia}{h}, \frac{ia}{h}]$ on imaginary axis

Forward Euler: (first method we saw)

$$\frac{U_j^{n+1} - U_j^n}{h} = -\frac{a}{2h} (U_{j+1}^n - U_{j-1}^n)$$

Absolute Stability Region for Euler: $|1 + k\lambda| < 1$

Eigenvalues of A always fall outside abs. stab region.

\Rightarrow method is not stable because eigenvalues $k\lambda$ do not lie in absolute stability region when we keep $\frac{h}{a}$ fixed.

Note: if we let $h \rightarrow 0$ faster than a then

$k\lambda \rightarrow 0$ so we get convergent method.

We can show this using previous theorem:

(Lax-Richtmyer stable & consistent) \Leftrightarrow convergent

Say we take $k = h^2$.

Look at:

$$B = I + kA$$

$$\underbrace{|1 + \underbrace{k\lambda p}_{\text{Im}}|}_{\in \mathbb{R}}^2 = 1 + |k\lambda p|^2 \stackrel{k=h^2}{\leq} 1 + \left(\frac{ka}{h}\right)^2 \leq 1 + a^2 h^2 = 1 + a^2 k$$

Thus we obtain bound:

(11)

$$\|I + kA\|_2^2 \leq 1 + a^2 k$$

$$\Rightarrow \|(I + kA)^n\|_2 \leq (1 + a^2 k)^{\frac{n}{2}} \stackrel{(*)}{\leq} e^{a^2 kn/2} \leq e^{a^2 T/2}$$

\uparrow
 $nk \leq T$

$\Rightarrow \|B^n\|$ is uniformly bounded for $nk \leq T$.

Inequality (*) comes from:

$$(1+t)^\alpha \leq e^{\alpha t} \quad \text{when } \alpha > 0, t > 0$$

which can be shown using calculus or

with Taylor: $(1+t)^\alpha = 1 + \alpha t + \frac{\alpha(\alpha-1)t^2}{2} + \dots$

$$e^{\alpha t} = 1 + \alpha t + \frac{(\alpha t)^2}{2!} + \dots$$

Here is another numerical method:

Leapfrog: use centered differences in time too:

$$\frac{U_j^{n+1} - U_j^{n-1}}{2k} = -\frac{a}{2h} (U_{j+1}^n - U_{j-1}^n)$$

\equiv 3 step, explicit method

\equiv second order in both space and time

Absolute stability region for this method (also called midpoint rule) is segment $[-1, 1]$ on imaginary axis

$$\Rightarrow -1 \leq \text{Im } k \lambda_p \leq 1$$

$$\Rightarrow \left| \frac{a k}{h} \right| \leq 1 \quad (\text{i.e. CFL cond.})$$

However:

- $k \lambda_p$ is always right on boundary of absolute stability region - \rightarrow marginal stability meaning small perturbations could lead to us falling outside abs. stab. region.
- all modes (frequencies) in sol are preserved (no decay or growth) non-dissipative method
- not all modes travel at same velocity: dispersive method

Lax-Friedrichs: revisited.

$$U_j^{n+1} = \frac{1}{2} (U_{j+1}^n + U_{j-1}^n) - \frac{ak}{2h} (U_{j+1}^n - U_{j-1}^n)$$

We rewrite the spatial average term as follows.

$$\frac{1}{2} (U_{j+1}^n + U_{j-1}^n) = U_j^n + \frac{1}{2} (U_{j-1}^n - 2U_j^n + U_{j+1}^n)$$

$$\Rightarrow U_j^{n+1} = U_j^n - \frac{ak}{2h} (U_{j+1}^n - U_{j-1}^n) + \underbrace{\frac{1}{2} (U_{j-1}^n - 2U_j^n + U_{j+1}^n)}_{\text{discrete Laplacian}}$$

Or to reveal more structure we rewrite L.F. as:

$$\frac{U_j^{n+1} - U_j^n}{k} + a \frac{U_{j+1}^n - U_{j-1}^n}{2h} = \frac{h^2}{2k} \frac{U_{j-1}^n - 2U_j^n + U_{j+1}^n}{h^2}$$

⇒ looks like solution to advection-diffusion eq:

$$u_t + a u_x = \underbrace{\epsilon u_{xx}}_{\downarrow}, \quad \text{with } \epsilon = \frac{h^2}{2k}$$

method incorporates some dissipation for stability purposes.

L.F. can be obtained by doing MOL on adv.-diff. eq and then using Euler's method:

MOL on adv.-diff eq:

$$U'(t) = A_\epsilon U(t)$$

where
 $\mathbb{R}^{m \times m+1}$

$$\exists A_\epsilon = -\frac{a}{2h} \begin{bmatrix} 0 & 1 & & & -1 \\ -1 & 0 & 1 & & \\ & -1 & 0 & 1 & \\ & & \ddots & \ddots & \ddots \\ 1 & & & -1 & 0 \end{bmatrix} + \frac{h^2}{2k} \begin{bmatrix} -2 & 1 & & & \\ 1 & -2 & 1 & & \\ & \ddots & \ddots & \ddots & \\ & & 1 & -2 & 1 \\ & & & 1 & -2 \end{bmatrix}$$

A

= circulant matrix

Since Laplacian is also a circulant matrix it has same eigenvectors as A , Therefore.

$$\begin{aligned} \lambda_p(A\epsilon) &= \lambda_p(A) + \epsilon \lambda_p(\text{Laplacian}) \\ &= \underbrace{-\frac{ia}{R} \sin(2\pi ph)}_{\text{diff. op. part}} - \underbrace{\frac{2\epsilon}{h^2} (1 - \cos(2\pi ph))}_{\text{Laplacian part}} \end{aligned}$$

in general we do not have $\lambda_p(A+B) = \lambda_p(A) + \lambda_p(B)$

The only way this can happen is when A and B are diagonalizable in same basis of eigenvectors.

Plotting $k \lambda_p(A\epsilon)$ in complex plane:

For L.F. $E = \frac{h^2}{2k}$ which means horizontal (115)

axis of ellipse is $[-2, 0] \subset$ abs. stab. region for Euler.

If in addition we assume CFL i.e. $\left| \frac{ak}{h} \right| < 1$,

then also vertical axis of ellipse \subset abs. stab. region for Euler.

\Rightarrow method is stable (provided CFL is satisfied)

Lax - Wendroff method

Idea: choose ϵ s.t. method is 2nd order accurate in both time and space.

(like leapfrog but with one step only and + dissipation)

(more commonly used)

$$U' = AU$$

$$U'' = AU' = AAU = A^2U$$

Then discretize system using Taylor's method:

$$\begin{aligned} U^{n+1} &= U^n + kU' + \frac{k^2}{2}U'' \\ &= U^n + kAU^n + \frac{k^2}{2}A^2U^n \end{aligned}$$

Computing A^2 gives:

$$U_j^{n+1} = U_j^n - \frac{ak}{2h} (U_{j+1}^n - U_{j-1}^n) + \frac{a^2k^2}{8h^2} (U_{j+1}^n - 2U_j^n + U_{j-1}^n)$$

Upwind methods

If we wanted to use one sided differences in x :

$$u_x(x_j, t) \approx \frac{1}{h} (U_j - U_{j-1})$$

$$u_x(x_j, t) \approx \frac{1}{h} (U_{j+1} - U_j)$$

we get two different methods:

① $U_j^{n+1} = U_j^n - \frac{ak}{h} (U_j^n - U_{j-1}^n)$ (first order in space and time)

② $U_j^{n+1} = U_j^n - \frac{ak}{h} (U_{j+1}^n - U_j^n)$

Which method should we use?

It depends on sign of a !!

True solution satisfies:

$$u(x_j, t+k) = u(x_j - ak, t)$$

i.e. origin is shifted to ak after one time step k .

So when we advance in time:

take values on left of U_j to preserve causality.

→ use method ①

take values on right of U_j to preserve causality.

→ use method ②

Stability analysis of upwind: we already did it!

Simply reuse arguments we used for L-F. since; upwind can be rewritten

$$\underline{\alpha > 0}: U_j^{n+1} = U_j^n - \frac{\alpha k}{2h} (U_{j+1}^n - U_{j-1}^n) + \frac{\alpha k}{2h} (U_{j+1}^n - 2U_j^n + U_{j-1}^n)$$

$$\underline{\alpha < 0}: U_j^{n+1} = U_j^n - \frac{\alpha k}{2h} (U_{j+1}^n - U_{j-1}^n) - \frac{\alpha k}{2h} (U_{j+1}^n - 2U_j^n + U_{j-1}^n)$$

$$= \frac{\epsilon k}{h^2}$$

$$\Rightarrow \boxed{\epsilon = \frac{|\alpha| h}{2}}$$

For stability we need (i.e. for ellipse being inside abs. stab. region for Euler)

$$\underbrace{\left| \frac{\alpha k}{h} \right| < 1}_{\text{CFL}} \quad \text{and} \quad -2 < \underbrace{-\frac{2\epsilon k}{h^2}}_{\frac{|\alpha k|}{h}} < 0$$

Note: getting signs wrong will cause blow up because inequality above is violated. (ellipse is on wrong side of imaginary axis)

Summary

(118)
