5.6 Unforced Mechanical Vibrations

The study of vibrating mechanical systems begins here with examples for unforced systems with one degree of freedom. The main example is a mass on a spring. The undamped, unforced cases are considered in a number of physical examples, which include the following: simple pendulum, compound pendulum, swinging rod, torsional pendulum, shockless auto, sliding wheel, rolling wheel.

Simple harmonic motion

Consider the spring-mass system of Figure 2, where \( x \) measures the signed distance from the equilibrium position of the mass. The spring is assumed to exert a force under both compression and elongation. Such springs are commonly used in automotive suspension systems, notably coil springs and leaf springs. In the case of coil springs, it is assumed that there is space between the coils, which allows the spring to exert bidirectional forces.

Hooke’s law. The basic physical law to be applied is:

\[
F = -kX.
\]

The number \( k \) is called Hooke’s constant for the spring. In the model of Figure 2, \( X = x(t) \) and \( k > 0 \). The minus sign accounts for the action of the force: the spring tries to restore the mass to the equilibrium state, so the vector force is directed toward the equilibrium position \( x = 0 \).

Newton’s second law. Specialized to the model in Figure 2, Newton’s second law says:

\[
F = ma
\]

The force \( F \) exerted by a mass \( m \) attached to a spring is \( F = ma \) where \( a = \frac{d^2x}{dt^2} \) is the acceleration of the mass.

The weight \( W = mg \) is defined in terms of the gravitational constant \( g = 32 \text{ ft/s}^2 \), 9.8 m/s\(^2\) or 980 cm/s\(^2\) where the mass \( m \) is given respectively in slugs, kilograms or grams. The weight is the force due to gravity and it has the appropriate units for a force: pounds in the case of the fps system of units.
Method of force competition. Hooke’s law \( F = -kx(t) \) and Newton’s second law \( F = mx''(t) \) give two independent equations for the force acting on the system. Equating competing forces implies that the signed displacement \( x(t) \) satisfies the free vibration equation
\[
mx''(t) + kx(t) = 0.
\]
It is also called the harmonic oscillator, especially in its equivalent form
\[
x''(t) + \omega^2x(t) = 0, \quad \omega^2 = \frac{k}{m}.
\]
In this context, \( \omega \) is the natural frequency of the free vibration. The harmonic oscillator is said to describe a simple harmonic motion \( x(t) \), known by the recipe to have the form \( x(t) = c_1 \cos \omega t + c_2 \sin \omega t \).

Phase-amplitude conversion. Given a simple harmonic motion \( x(t) = c_1 \cos \omega t + c_2 \sin \omega t \), as in Figure 3, define amplitude \( A \) and phase angle \( \alpha \) by the formulas
\[
A = \sqrt{c_1^2 + c_2^2}, \quad c_1 = A \cos \alpha \quad \text{and} \quad c_2 = A \sin \alpha.
\]
Then the simple harmonic motion has the phase-amplitude form
\[
(1) \quad x(t) = A \cos(\omega t - \alpha).
\]
To directly obtain (1) from trigonometry, use the trigonometric identity \( \cos(a - b) = \cos a \cos b + \sin a \sin b \) with \( a = \omega t \) and \( b = \alpha \). It is known from trigonometry that \( x(t) \) has period \( 2\pi/\omega \) and phase shift \( \alpha/\omega \). A full period is called a cycle and a half-period a semicycle. The frequency \( \omega/(2\pi) \) is the number of complete cycles per second, or the reciprocal of the period.

The phase shift is the amount of horizontal translation required to shift the cosine curve \( \cos(\omega t - \alpha) \) so that its graph is atop \( \cos(\omega t) \). To find the phase shift from \( x(t) \), set the argument of the cosine term to zero, then solve for \( t \).

To solve for \( \alpha \geq 0 \) in the equations \( c_1 = A \cos \alpha, \ c_2 = A \sin \alpha \), first compute numerically by calculator the radian angle \( \phi = \arctan(c_2/c_1) \), which is in the range \(-\pi/2 \) to \( \pi/2 \). Quadrantal angle rules must be applied when \( c_1 = 0 \), because calculators return an error code for division.
by zero. A common error is to set $\alpha$ equal to $\phi$. Not just the violation of $\alpha \geq 0$ results — the error is a fundamental one, due to trigonometric intricacies, causing us to consider the equations $c_1 = A\cos\alpha$, $c_2 = A\sin\alpha$ in order to construct the answer for $\alpha$:

$$\alpha = \begin{cases} 
\phi & (c_1, c_2) \text{ in quadrant I}, \\
\phi + \pi & (c_1, c_2) \text{ in quadrant II}, \\
\phi + \pi & (c_1, c_2) \text{ in quadrant III}, \\
\phi + 2\pi & (c_1, c_2) \text{ in quadrant IV}.
\end{cases}$$

**Visualization of harmonic motion.** A simple harmonic motion can be obtained graphically by means of the experiment shown in Figure 4, in which an undamped spring-mass system has an attached pen that writes on a moving paper chart. The chart produces the simple harmonic motion $x(t) = c_1 \cos \omega t + c_2 \sin \omega t$ or equivalently $x(t) = A \cos(\omega t - \phi)$.

![Figure 4. A moving paper chart records the vertical motion of a mass on a spring by means of an attached pen.](image)

**Applications**

We will consider various incarnations of the pendulum. The illustrations end with applications to auto suspension systems and rolling wheels.

**The simple pendulum.** A pendulum is constructed from a thin massless wire or rod of length $L$ and a body of mass $m$, as in Figure 5. Along the circular arc travelled by the mass, the velocity is $ds/dt$ where $s = L\theta(t)$ is arclength. The acceleration is $L\theta''(t)$. Newton’s second law for the force along this arc is $F = mL\theta''(t)$. Another relation for the force can be found by resolving the vector gravitational force $mg$ into its normal and tangential components. By trigonometry, the tangential component gives a second force equation $F = -mg \sin \theta(t)$. Equating competing forces and cancelling $m$ results in the pendulum equation

$$\theta''(t) + \frac{g}{L} \sin \theta(t) = 0.$$  

Because the mass $m$ cancels from the equation, the pendulum oscillation depends only upon the length of the string and not upon the mass!
The approximation \( \sin u \approx u \), valid for small angles \( u \), is applied to (2). The result is the **linearized pendulum**

\[
\theta''(t) + \frac{g}{L} \theta(t) = 0.
\]

This equation is indistinguishable from the classical harmonic oscillator, except for variable names. The characteristic solution is \( \theta(t) = A \cos(\omega t - \alpha) \), \( \omega^2 = g/L \).

**The physical pendulum.** The compound pendulum or physical pendulum is a rigid body of total mass \( m \) having center of mass \( C \) which is suspended from a fixed origin \( O \) – see Figure 6.

The distance from \( O \) to \( C \) is denoted \( d > 0 \). The gravity vector \( \vec{g} \) makes angle \( \theta \) with segment \( \overline{OC} \) and it supplies a restoring torque of magnitude \( F = -mgd \sin \theta \). Newton’s second law gives a second force equation \( F = I \theta''(t) \) where \( I \) is the torque of the rigid body about \( O \). Force competition results in the **compound pendulum**

\[
\theta''(t) + \frac{mgd}{I} \sin \theta(t) = 0.
\]

Using \( \sin u \approx u \) gives a harmonic oscillator known as the linearized compound pendulum

\[
\theta''(t) + \omega^2 \theta(t) = 0, \quad \omega = \sqrt{\frac{mgd}{I}}.
\]

**The swinging rod.** As depicted in Figure 7, a swinging rod is a special case of the compound pendulum.
5.6 Unforced Mechanical Vibrations

The torque \( I = mL^2/3 \) and center of mass distance \( d = L/2 \) are routine calculus calculations. Then \( mgd/I = 3mgL/2mL^2 = 3g/2L \). Applying (4) gives the swinging rod

\[
\theta''(t) + \frac{3g}{2L} \sin \theta(t) = 0
\]

and applying (5) gives the linearized swinging rod

\[
\theta''(t) + \omega^2 \theta(t) = 0, \quad \omega = \sqrt{\frac{3g}{2L}}.
\]

The torsional pendulum. A model for a balance wheel in a watch, a gavanometer or a Cavendish torsional balance is the torsional pendulum, which is a rigid body suspended by a wire – see Figure 8. The twisted wire exerts a restoring force \( F = -\kappa \theta_0 \) when the body is rotated through angle \( \theta_0 \). There is no small angle restriction on this restoring force, because it acts in the spirit of Hooke’s law like a linear spring restoring force. The model uses the Newton’s second law force relation \( F = I\theta''_0(t) \), as in the physical pendulum, but the restoring force is \( F = -\kappa \theta_0 \), giving the torsional pendulum

\[
\theta''_0(t) + \omega^2 \theta_0(t) = 0, \quad \omega = \sqrt{\frac{\kappa}{I}}.
\]

Shockless auto. An auto loaded with several occupants is supported by four coil springs, as in Figure 9, but all of the shock absorbers are worn out. The simplistic model \( mx''(t) + kx(t) = 0 \) will be applied. The plan is to estimate the number of seconds it takes for one complete oscillation. This is the time between two consecutive bottom–outs of the auto.\(^1\)

Assume the car plus occupants has mass 1350 Kg. Let each coil spring have Hooke’s constant \( k = 20000 \) Newtons per meter. The load is divided

\[^1\]Los Angeles patrol officers gave traffic citations to teenagers who disabled the shocks on their cars. The extreme bronc–buster ride distinguished the modified cars cruising California boulevards.
among the four springs equally, so each spring supports \( m = \frac{1350}{4} \text{ Kg} \). We will find the natural frequency of vibration \( \omega \). Then the number of seconds for one complete oscillation is the period \( T = \frac{2\pi}{\omega} \) seconds. The oscillation model for one spring is

\[
\frac{1350}{4} x''(t) + 20000x(t) = 0.
\]

In the harmonic oscillator form \( x'' + \omega^2 x = 0 \), \( \omega^2 = \frac{20000(4)}{1350} = 59.26 \) and therefore \( \omega = 7.70 \), \( T = \frac{2\pi}{\omega} = 0.82 \) seconds.

**Rolling wheel on a spring.** A wheel of total mass \( m \) and radius \( R \) is attached at its center to a spring of Hooke’s constant \( k \), as in Figure 10. The wheel rolls without slipping.

![Figure 10. A rolling wheel attached to a spring.](image)

**Modelling.** Let \( x(t) \) be the elongation of the spring from equilibrium, \( x > 0 \) corresponding to the wheel rolling to the right and \( x < 0 \) corresponding to the wheel rolling to the left.

If the wheel slides frictionless, then the model is \( mx''(t) + kx(t) = 0 \). But a wheel that rolls without slipping has inertia, and consideration of this physical difference will be shown to give the **rolling wheel** equation

\[
mx''(t) + \frac{2}{3} kx(t) = 0.
\]

A curious consequence is that \( x(t) \) is identical to the frictionless sliding wheel with spring constant reduced from \( k \) to \( 2k/3 \). This makes sense physically, because the action of the rolling wheel is to reduce the stiffness of the spring.

The derivation is based upon the energy conservation law

\[
\text{Kinetic} + \text{Potential} = \text{constant}.
\]

The kinetic energy \( T \) is the sum of two energies, \( T_1 = \frac{1}{2}mv^2 \) for translation and \( T_2 = \frac{1}{2}I\omega^2 \) for the rolling wheel, whose inertia is \( I = \frac{1}{2}mR^2 \). The velocity is \( v = R\omega = x'(t) \). Algebra gives \( T = T_1 + T_2 = \frac{3}{2}mv^2 \). The potential energy is \( K = \frac{1}{2}kx^2 \) for a spring of Hooke’s constant \( k \). Application of the energy conservation law \( T + K = c \) gives the equation \( \frac{3}{4}m(x'(t))^2 + \frac{1}{2}k(x(t))^2 = c \). Differentiate this equation on \( t \) to obtain \( \frac{3}{2}mx'(t)x''(t) + kx(t)x'(t) = 0 \), then cancel \( x'(t) \) to give (9).
Exercises 5.6

Simple harmonic motion. Determine the model equation $mx''(t) + kx(t) = 0$, the natural frequency $\omega = \sqrt{k/m}$, the period $2\pi/\omega$ and the solution $x(t)$ for the following spring–mass systems.

1. A mass of 4 Kg attached to a spring of Hooke’s constant 20 Newtons per meter starts from equilibrium plus 0.05 meters with velocity 0.

2. A mass of 2 Kg attached to a spring of Hooke’s constant 20 Newtons per meter starts from equilibrium plus 0.07 meters with velocity 0.

3. A mass of 2 Kg is attached to a spring that elongates 20 centimeters due to a force of 10 Newtons. The motion starts at equilibrium with velocity $-5$ meters per second.

4. A mass of 4 Kg is attached to a spring that elongates 20 centimeters due to a force of 12 Newtons. The motion starts at equilibrium with velocity $-8$ meters per second.

5. A mass of 3 Kg is attached to a coil spring that compresses 2 centimeters when 1 Kg rests on the top coil. The motion starts at equilibrium plus 3 centimeters with velocity 0.

6. A mass of 4 Kg is attached to a coil spring that compresses 2 centimeters when 2 Kg rests on the top coil. The motion starts at equilibrium plus 4 centimeters with velocity 0.

Phase–amplitude forms. Solve the given differential equation and report the solution in phase–amplitude form $x(t) = A \cos(\omega t - \alpha)$ with $A > 0$ and $0 \leq \alpha < 2\pi$.

7. $x'' + 4x = 0$, $x(0) = 1$, $x'(0) = -1$

8. $x'' + 4x = 0$, $x(0) = 1$, $x'(0) = 1$

9. $x'' + 16x = 0$, $x(0) = 2$, $x'(0) = -1$

10. $x'' + 16x = 0$, $x(0) = -2$, $x'(0) = -1$

11. $5x'' + 11x = 0$, $x(0) = -4$, $x'(0) = 1$

12. $5x'' + 11x = 0$, $x(0) = -4$, $x'(0) = -1$

13. $x'' + x = 0$, $x(0) = 1$, $x'(0) = -2$

14. $x'' + x = 0$, $x(0) = -1$, $x'(0) = 2$

Pendulum. The formula
\[
\frac{P_1}{P_2} = \frac{R_1}{R_2} \sqrt{\frac{L_1}{L_2}}
\]
is valid for the periods $P_1$, $P_2$ of two pendulums of lengths $L_1$, $L_2$ located at distances $R_1$, $R_2$ from the center of the earth. The formula implies that a pendulum can be used to find the radius of the earth at a location. It is also useful for designing a pendulum clock adjustment screw.

15. Derive the formula, using the gravitational relation $g = GM/R^2$ and the period formula $P = 2\pi/\omega$, where $\omega = \sqrt{g/L}$.

16. A pendulum clock taken on a voyage loses 2 minutes a day compared to its exact timing at home. Determine the altitude change at the destination.

17. A pendulum clock with adjustable length $L$ loses 3 minutes per day when $L = 30$ inches. What length $L$ adjusts the clock to perfect time?
18. A pendulum clock with adjustable length \( L \) loses 4 minutes per day when \( L = 30 \) inches. What fineness length \( F \) is required for a \( 1/4 \)-turn of the adjustment screw, in order to have \( 1/4 \)-turns of the screw set the clock to perfect time plus or minus one second per day?
