Math 2250
Maple Lab 8: Earthquake project
Spring 2008

Name ____________________________________   Class Time __________

Project 8. Solve problems L8.1 to L8.5. The problem headers:

_______   PROBLEM L8.1. EARHQUAKE MODEL FOR A BUILDING.
_______   PROBLEM L8.2. TABLE OF NATURAL FREQUENCIES AND PERIODS.
_______   PROBLEM L8.3. UNDETERMINED COEFFICIENTS STEADY-STATE SOL
_______   PROBLEM L8.4. PRACTICAL RESONANCE.
_______   PROBLEM L8.5. EARTHQUAKE DAMAGE.

SIX FLOOR Model.
Refer to the textbook of Edwards-Penney, section 7.4, page 437.
Consider a building with six floors each weighing 50 tons. Each
floor corresponds to a restoring Hooke's force with constant k=5
tons/foot. Assume that ground vibrations from the earthquake are
modeled by (1/4)cos(wt) with period T=2*Pi/w.

PROBLEM L8.1. BUILDING MODEL FOR AN EARTHQUAKE.
Model the 6-floor problem in Maple.
Define the 6 by 6 mass matrix M and Hooke's matrix K for this system
and convert Mx''=Kx into the system x''=Ax where A is defined by
textbook equation (1), page 437.

Sanity check: Mass m=3125, and the 6x6 matrix contains fraction 16/5.

Then find the eigenvalues of the matrix A to six digits, using the
Maple command "eigenvals(A)."
Sanity check: All six eigenvalues should be negative.

```
# Sample Maple code for a model with 4 floors.
# Use maple help to learn about evalf and eigenvals.
# A:=matrix([ [-20,10,0,0], [10,-20,10,0],
[0,10,-20,10],[0,0,10,-10]]);
# with(linalg): evalf(eigenvals(A));

# Problem L8.1
# Define k, m and the 6x6 matrix A.
# with(linalg): evalf(eigenvals(A));
```

PROBLEM L8.2. TABLE OF NATURAL FREQUENCIES AND PERIODS.
Refer to figure 7.4.17, page 437.

Find the natural angular frequencies omega=sqrt(-lambda) for the
six story building and also the corresponding periods
2PI/omega, accurate to six digits. Display the answers in a table .
Compare with answers in Figure 7.4.17, page 437, for the 7-story case.

```
# Sample code for a 4x3 table, 4-story building.
# Use maple help to learn about nops and printf.
```

```
# ev:=[-10,-1.206147582,-35.32088886,-23.47296354]: n:=nops(ev):
# Omega:=lambda -> sqrt(-lambda):
# format:="%10.6f  %10.6f  %10.6f\n":
# seq(printf(format,ev[i],Omega(ev[i]),2*evalf(Pi)/Omega(ev[i])),
i=1..n);

# Problem L8.2
# ev:=[fill this in]: n:=nops(ev):
# Omega:=lambda -> sqrt(-lambda): format:="%10.6f  %10.6f  %10.6f\n":
#
seq(printf(format,ev[i],Omega(ev[i]),2*evalf(Pi)/Omega(ev[i])),i=1..n)
;

PROBLEM  L8.3. UNDETERMINED COEFFICIENTS
              STEADY-STATE PERIODIC SOLUTION.
Consider the forced equation  x'=Ax+cos(wt)b  where  b  is a constant
vector. The earthquake's ground vibration is accounted for by the
extra term cos(wt)b, which has period  T=2Pi/w.
The solution  x(t)  is  the  6-vector of excursions from equilibrium
of the corresponding 6 floors.
Sought here is not the general solution, which certainly contains
transient terms, but rather the steady-state periodic solution, which
is known from the theory to have the form x(t)=cos(wt)c for some
vector  c  that depends only on  A  and  b.

Define  b:=0.25*w*w*vector([1,1,1,1,1,1]):  in Maple and find the
vector  c  in the undetermined coefficients solution  x(t)=cos(wt)c.
Vector  c  depends on w. As outlined in the textbook, vector  c
can be found by solving the linear algebra problem  -w^2 c = Ac + b;
see page 433. Don't print  c, as it is too complex; instead, print
c[1] as an illustration.

#Sample code for defining  b and A, then solving for  c
#in the 4-floor case.
# See maple help to learn about vector and linsolve.
#  w:='w': u:=w*w: b:=0.25*u*vector([1,1,1,1]):
#  A:=matrix([ [-20,10,0,0], [10,-20,10,0],
[0,10,-20,10],[0,0,10,-10]]);
# Au:=evalm(A+u*diag(1,1,1,1));
#  c:=linsolve(Au,-b):
#  evalf(c[1],2);

# PROBLEM L8.3
# Define w, u, b, A, Au, c
# evalf(c[1],2);

PROBLEM L8.4. PRACTICAL RESONANCE.
Consider the forced equation  x'=Ax+cos(wt)b  of L8.3 above with
b:=0.25*w*w*vector([1,1,1,1,1,1]).
Practical resonance can occur if a component of  x(t)  has large
amplitude compared to the vector norm of b. For example, an earthquake
might cause a small 3-inch excursion on level ground, but the
building's floors might have 50-inch excursions, enough to destroy
```

```
the building.

Let Max(c) denote the maximum modulus of the components of vector c.
Plot  g(T)=Max(c(w)) with w=(2*Pi)/T for periods T=0 to T=6, ordinates
Max=0 to Max=10, the vector c(w) being the answer produced in L8.3
above.  Compare your figure to the textbook Figure 7.4.18, page 438.

# Sample maple code to define the function Max(c), 4-floor building.
# Use maple help to learn about norm, vector, subs and linsolve.
#  with(linalg):
#  w:='w': Max:= c -> norm(c,infinity); u:=w*w:
#  b:=0.25*w*w*vector([1,1,1,1]):
# A:=matrix([ [-20,10,0,0], [10,-20,10,0], [0,10,-20,10],
[0,0,10,-10]]);
#  Au:=evalm(A+u*diag(1,1,1,1));
#  C:=ww -> subs(w=ww,linsolve(Au,-b)):
#  plot(Max(C(2*Pi/r)),r=0..6,0..10,numpoints=150);

# PROBLEM L8.4. WARNING: Save your file often!!!
# w:='w': Max:= c -> norm(c,infinity): u:=w*w:
# Define b
# Define A
# Define Au
# Define C
# plot(Max(C(2*Pi/r)),r=0..6,0..10,numpoints=150);

PROBLEM L8.5. EARTHQUAKE DAMAGE.
The maximum amplitude plot of L8.4 can be used to detect the
of earthquake damage for a given
ground vibration of period T.  A ground vibration (1/4)cos(wt),
T=2*Pi/w, will be assumed, as in L8.4.

(a) Replot the amplitudes in L8.4 for periods 1.5 to 5.5 and
amplitudes 5 to 10.
There will be five spikes.
(b) Create five zoom-in plots, one for each spike, choosing a
T-interval that shows the full spike.
(c) Determine from the five zoom-in plots approximate intervals for
the period  T  such that some floor in the building will undergo
excursions from equilibrium in excess of 5 feet.

# Example: Zoom-in on a spike for amplitudes 5 feet to 10 feet,
#periods 1.97 to 2.01.
#with(linalg): w:='w': Max:= c -> norm(c,infinity); u:=w*w:
#Au:=matrix([ [-20+u,10,0,0], [10,-20+u,10,0],
[0,10,-20+u,10],[0,0,10,-10+u]]);
#b:=0.25*w*w*vector([1,1,1,1]):
#C:=ww -> subs(w=ww,linsolve(Au,-b)):
#plot(Max(C(2*Pi/r)),r=1.97..2,01,5..10,numpoints=150);

# PROBLEM L8.5. WARNING: Save your file often!!
#(a) Re-plot the five spikes.
# plot(Max(C(2*Pi/r)),r=1.5..5.5,5..10,numpoints=150);
```

```
#(b) Plot five zoom-in graphs.
# one:=1.79..1.83:plot(Max(C(2*Pi/r)),r=one,5..10,numpoints=150);
# two:=???:plot(Max(C(2*Pi/r)),r=two,5..10,numpoints=150);
# three:=???:plot(Max(C(2*Pi/r)),r=three,5..10,numpoints=150);
# four:=???:plot(Max(C(2*Pi/r)),r=four,5..10,numpoints=150);
# five:=???:plot(Max(C(2*Pi/r)),r=five,5..10,numpoints=150);
#(c) Print period ranges.
# PeriodRanges:=[one,two,three,four,five];
```
