

## Basic Theory of Linear Differential Equations

- Picard-Lindelöf Existence-Uniqueness
  - Vector  $n$ th Order Theorem
  - Second Order Linear Theorem
  - Higher Order Linear Theorem
- Homogeneous Structure
- Recipe for Constant-Coefficient Linear Homogeneous Differential Equations
  - First Order
  - Second Order
  - $n$ th Order
- Superposition
- Non-Homogeneous Structure

### Theorem 1 (Picard-Lindelöf Existence-Uniqueness)

Let the  $n$ -vector function  $\mathbf{f}(x, \mathbf{y})$  be continuous for real  $x$  satisfying  $|x - x_0| \leq a$  and for all vectors  $\mathbf{y}$  in  $\mathbf{R}^n$  satisfying  $\|\mathbf{y} - \mathbf{y}_0\| \leq b$ . Additionally, assume that  $\partial \mathbf{f} / \partial \mathbf{y}$  is continuous on this domain. Then the initial value problem

$$\begin{cases} \mathbf{y}' = \mathbf{f}(x, \mathbf{y}), \\ \mathbf{y}(x_0) = \mathbf{y}_0 \end{cases}$$

has a unique solution  $\mathbf{y}(x)$  defined on  $|x - x_0| \leq h$ , satisfying  $\|\mathbf{y} - \mathbf{y}_0\| \leq b$ , for some constant  $h$ ,  $0 < h < a$ .

---

The unique solution can be written in terms of the *Picard Iterates*

$$y_{n+1}(x) = y_0 + \int_{x_0}^x \mathbf{f}(t, y_n(t)) dt, \quad y_0(x) \equiv y_0,$$

as the formula

$$\mathbf{y}(x) = \mathbf{y}_n(x) + \mathbf{R}_n(x), \quad \lim_{n \rightarrow \infty} \mathbf{R}_n(x) = \mathbf{0}.$$

The formula means  $\mathbf{y}(x)$  can be computed as the iterate  $\mathbf{y}_n(x)$  for large  $n$ .

## **Theorem 2 (Second Order Linear Picard-Lindelöf Existence-Uniqueness)**

Let the coefficients  $a(x)$ ,  $b(x)$ ,  $c(x)$ ,  $f(x)$  be continuous on an interval  $J$  containing  $x = x_0$ . Assume  $a(x) \neq 0$  on  $J$ . Let  $g_1$  and  $g_2$  be real constants. The initial value problem

$$\begin{cases} a(x)y'' + b(x)y' + c(x)y = f(x), \\ y(x_0) = g_1, \\ y'(x_0) = g_2 \end{cases}$$

has a unique solution  $y(x)$  defined on  $J$ .

### Theorem 3 (Higher Order Linear Picard-Lindelöf Existence-Uniqueness)

Let the coefficients  $a_0(x), \dots, a_n(x), f(x)$  be continuous on an interval  $J$  containing  $x = x_0$ . Assume  $a_n(x) \neq 0$  on  $J$ . Let  $g_1, \dots, g_n$  be constants. Then the initial value problem

$$\begin{cases} a_n(x)y^{(n)}(x) + \dots + a_0(x)y = f(x), \\ y(x_0) = g_1, \\ y'(x_0) = g_2, \\ \vdots \\ y^{(n-1)}(x_0) = g_n \end{cases}$$

has a unique solution  $y(x)$  defined on  $J$ .

#### **Theorem 4 (Homogeneous Structure 2nd Order)**

The homogeneous equation  $a(x)y'' + b(x)y' + c(x)y = 0$  has a general solution of the form

$$y_h(x) = c_1y_1(x) + c_2y_2(x),$$

where  $c_1, c_2$  are arbitrary constants and  $y_1(x), y_2(x)$  are independent solutions.

---

#### **Theorem 5 (Homogeneous Structure $n$ th Order)**

The homogeneous equation  $a_n(x)y^{(n)} + \dots + a_0(x)y = 0$  has a general solution of the form

$$y_h(x) = c_1y_1(x) + \dots + c_ny_n(x),$$

where  $c_1, \dots, c_n$  are arbitrary constants and  $y_1(x), \dots, y_n(x)$  are independent solutions.

### **Theorem 6 (First Order Recipe)**

Let  $a$  and  $b$  be constants,  $a \neq 0$ . Let  $r_1$  denote the root of  $ar + b = 0$  and construct its corresponding atom  $e^{r_1x}$ . Multiply the atom by arbitrary constant  $c_1$ . Then  $y = c_1e^{r_1x}$  is the general solution of the first order equation

$$ay' + by = 0.$$

---

The equation  $ar + b = 0$ , called the *characteristic equation*, is found by the formal replacements  $y' \rightarrow r$ ,  $y \rightarrow 1$  in the differential equation  $ay' + by = 0$ .

### Theorem 7 (Second Order Recipe)

Let  $a \neq 0$ ,  $b$  and  $c$  be real constant. Then the general solution of

$$ay'' + by' + cy = 0$$

is given by the expression  $y = c_1y_1 + c_2y_2$ , where  $c_1, c_2$  are arbitrary constants and  $y_1, y_2$  are two atoms constructed as outlined below from the roots of the *characteristic equation*

$$ar^2 + br + c = 0.$$

---

The characteristic equation  $ar^2 + br + c = 0$  is found by the formal replacements  $y'' \rightarrow r^2, y' \rightarrow r, y \rightarrow 1$  in the differential equation  $ay'' + by' + cy = 0$ .

## Construction of Atoms for Second Order

---

The atom construction from the roots  $r_1, r_2$  of  $ar^2 + br + c = 0$  is based on Euler's theorem below, organized by the sign of the discriminant  $D = b^2 - 4ac$ .

$D > 0$  (Real distinct roots  $r_1 \neq r_2$ )

$$y_1 = e^{r_1 x}, \quad y_2 = e^{r_2 x}.$$

$D = 0$  (Real equal roots  $r_1 = r_2$ )

$$y_1 = e^{r_1 x}, \quad y_2 = x e^{r_1 x}.$$

$D < 0$  (Conjugate roots  $r_1 = \bar{r}_2 = A + iB$ )

$$y_1 = e^{Ax} \cos(Bx),$$

$$y_2 = e^{Ax} \sin(Bx).$$

---

### Theorem 8 (Euler's Theorem)

The atom  $y = x^k e^{Ax} \cos(Bx)$  is a solution of  $ay'' + by' + cy = 0$  if and only if  $r_1 = A + iB$  is a root of the characteristic equation  $ar^2 + br + c = 0$  and  $(r - r_1)^k$  divides  $ar^2 + br + c$ .

---

Valid also for  $\sin(Bx)$  when  $B > 0$ . Always,  $B \geq 0$ . For second order, only  $k = 1, 2$  are possible.

---

Euler's theorem is valid for any order differential equation: replace the equation by  $a_n y^{(n)} + \dots + a_0 y = 0$  and the characteristic equation by  $a_n r^n + \dots + a_0 = 0$ .

### Theorem 9 (Recipe for $n$ th Order)

Let  $a_n \neq 0, \dots, a_0$  be real constants. Let  $y_1, \dots, y_n$  be the list of  $n$  distinct atoms constructed by Euler's Theorem from the  $n$  roots of the characteristic equation

$$a_n r^n + \dots + a_0 = 0.$$

Then  $y_1, \dots, y_n$  are independent solutions of

$$a_n y^{(n)} + \dots + a_0 y = 0$$

and all solutions are given by the general solution formula

$$y = c_1 y_1 + \dots + c_n y_n,$$

where  $c_1, \dots, c_n$  are arbitrary constants.

---

The characteristic equation is found by the formal replacements  $y^{(n)} \rightarrow r^n, \dots, y' \rightarrow r, y \rightarrow 1$  in the differential equation.

### **Theorem 10 (Superposition)**

The homogeneous equation  $a(x)y'' + b(x)y' + c(x)y = 0$  has the *superposition property*:

If  $y_1, y_2$  are solutions and  $c_1, c_2$  are constants, then the combination  $y(x) = c_1y_1(x) + c_2y_2(x)$  is a solution.

The result implies that *linear combinations of solutions are also solutions*.

---

The theorem applies as well to an  $n$ th order linear homogeneous differential equation with continuous coefficients  $a_0(x), \dots, a_n(x)$ .

---

The result can be extended to more than two solutions. If  $y_1, \dots, y_k$  are solutions of the differential equation, then all linear combinations of these solutions are also solutions.

---

The solution space of a linear homogeneous  $n$ th order linear differential equation is a subspace  $S$  of the vector space  $V$  of all functions on the common domain  $J$  of continuity of the coefficients.

### Theorem 11 (Non-Homogeneous Structure 2nd Order)

The non-homogeneous equation  $a(x)y'' + b(x)y' + c(x)y = f(x)$  has general solution

$$y(x) = y_h(x) + y_p(x),$$

where

- $y_h(x)$  is the general solution of the homogeneous equation  $a(x)y'' + b(x)y' + c(x)y = 0$ , and
- $y_p(x)$  is a particular solution of the nonhomogeneous equation  $a(x)y'' + b(x)y' + c(x)y = f(x)$ .

---

The theorem is valid for higher order equations: the general solution of the non-homogeneous equation is  $y = y_h + y_p$ , where  $y_h$  is the general solution of the homogeneous equation and  $y_p$  is *any* particular solution of the non-homogeneous equation.

#### An Example

---

For equation  $y'' - y = 10$ , the homogeneous equation  $y'' - y = 0$  has general solution  $y_h = c_1e^x + c_2e^{-x}$ . Select  $y_p = -10$ , an equilibrium solution. Then  $y = y_h + y_p = c_1e^x + c_2e^{-x} - 10$ .

### **Theorem 12 (Non-Homogeneous Structure $n$ th Order)**

The non-homogeneous equation  $a_n(x)y^{(n)} + \cdots + a_0(x)y = f(x)$  has general solution

$$y(x) = y_h(x) + y_p(x),$$

where

- $y_h(x)$  is the general solution of the homogeneous equation  $a_n(x)y^{(n)} + \cdots + a_0(x)y = 0$ , and
- $y_p(x)$  is a particular solution of the nonhomogeneous equation  $a_n(x)y^{(n)} + \cdots + a_0(x)y = f(x)$ .
