Math 2250-004

Week 15: Section 7.4, mass-spring systems.

These are notes for Monday and Tuesday (and possibly for part of Wednesday). There will also be course review notes for Wednesday, posted later.

## Mon Dec 5

7.4 Mass-spring systems and untethered mass-spring trains.

In your homework and lab for this week you study special cases of the spring systems below, with no damping. Although we draw the pictures horizontally, they would also hold in vertical configuration if we measure displacements from equilibrium in the underlying gravitational field.

Let's make sure we understand why the natural system of DEs and IVP for this system is

$$\begin{split} m_1 \, x_1^{\; \prime \; \prime} \, (t) &= -k_1 \, x_1 + k_2 \big( x_2 - x_1 \big) \\ m_2 \, x_2^{\; \prime \; \prime} \, (t) &= -k_2 \big( x_2 - x_1 \big) - k_3 \, x_2 \\ x_1 \, (0) &= a_1, \quad x_1^{\; \prime} \, (0) = a_2 \\ x_2 \, (0) &= b_1, \quad x_2^{\; \prime} \, (0) = b_2 \end{split}$$

Exercise 1a) What is the dimension of the solution space to this homogeneous linear system of differential equations? Why?

<u>1b)</u> What if one had a configuration of n masses in series, rather than just 2 masses? What would the dimension of the homogeneous solution space be in this case? Why? Examples:

We can write the system of DEs for the system at the top of page 1 in matrix-vector form: 
$$\begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix} \begin{bmatrix} x_1''(t) \\ x_2''(t) \end{bmatrix} = \begin{bmatrix} -k_1 - k_2 & k_2 \\ k_2 & -k_2 - k_3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}.$$

We denote the diagonal matrix on the left as the "mass matrix" M, and the matrix on the right as the spring constant matrix K (although to be completely in sync with Chapter 5 it would be better to call the spring matrix -K). All of these configurations of masses in series with springs can be written as

$$M\underline{x}^{\prime\prime}(t) = K\underline{x}$$
.

If we divide each equation by the reciprocal of the corresponding mass, we can solve for the vector of accelerations:

$$\begin{bmatrix} x_1''(t) \\ x_2''(t) \end{bmatrix} = \begin{bmatrix} -\frac{k_1 + k_2}{m_1} & \frac{k_2}{m_1} \\ \frac{k_2}{m_2} & -\frac{k_2 + k_3}{m_2} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix},$$

which we write as

$$\underline{\boldsymbol{x}}^{\prime\prime}(t) = A\,\underline{\boldsymbol{x}}$$
.

(You can think of A as the "acceleration" matrix.)

Notice that the simplification above is mathematically identical to the algebraic operation of multiplying the first matrix equation by the (diagonal) inverse of the diagonal mass matrix M. In all cases:

$$M\underline{x}^{\prime\prime}(t) = K\underline{x} \implies \underline{x}^{\prime\prime}(t) = A\underline{x}$$
, with  $A = M^{-1}K$ .

How to find a basis for the solution space to conserved-energy mass-spring systems of DEs

$$\underline{x}^{\prime\prime}(t) = A \underline{x}$$
.

Based on our previous experiences, the natural thing for this homogeneous system of linear differential equations is to try and find a basis of solutions of the form

$$\underline{\boldsymbol{x}}(t) = \mathrm{e}^{rt}\underline{\boldsymbol{y}}$$

We would maybe also think about first converting the second order system to an equivalent first order system of twice as many DE's, one for for each position function and one for each velocity function. But let's try the substitution directly, in analogy to what we did for higher order single linear differential equations back in Chapter 5.

Now, in the present case of systems of masses and springs we are assuming there is no damping. Thus, the total energy - consisting of the sum of kinetic and potential energy - will always be conserved. Any two complex solutions of the form

$$\underline{x}(t) = e^{rt}v^{\pm} = e^{(a \pm \omega i)t}v^{\pm}$$

would yield two real solutions  $\underline{X}(t)$ ,  $\underline{Y}(t)$  where

$$\underline{\mathbf{x}}(t) = \underline{\mathbf{X}}(t) \pm i \underline{\mathbf{Y}}(t)$$
.

Because of conservation of energy (TE = KE + PE must be constant), neither  $\underline{X}(t)$  nor  $\underline{Y}(t)$  can grow or decay exponentially - if a solution grew exponentially the total energy would also grow exponentially; if it decayed exponentially the total energy would decay exponentially. SO, we must have a = 0. In other words, in order for the total energy to remain constant we must actually have

$$\underline{\mathbf{x}}(t) = \mathrm{e}^{i\,\omega\,t}\underline{\mathbf{y}}$$
.

Substituting this x(t) into the homogeneous DE

$$\underline{x}^{\prime\prime}(t) = A \underline{x}$$

yields the necessary condition

$$-\omega^2 e^{i \omega t} v = e^{i \omega t} A v$$

 $-\omega^2 e^{i\omega t} \underline{\mathbf{v}} = e^{i\omega t} A \underline{\mathbf{v}} \quad .$  So  $\underline{\mathbf{v}}$  must be an eigenvector, with non-positive eigenvalue  $\lambda = -\omega^2$ ,

$$A \underline{\mathbf{v}} = -\boldsymbol{\omega}^2 \underline{\mathbf{v}}$$
.

And since row reduction will find real eigenvectors for real eigenvalues, we can find eigenvectors v with real entries. And the two complex solutions

$$\underline{\mathbf{x}}(t) = e^{\pm i\omega t}\underline{\mathbf{y}} = \cos(\omega t)\underline{\mathbf{y}} \pm i\sin(\omega t)\underline{\mathbf{y}}$$

yield the two real solutions

$$\underline{X}(t) = \cos(\omega t)\underline{v}, \quad \underline{Y}(t) = \sin(\omega t)\underline{v}.$$

So, we skip the exponential solutions altogether, and go directly to finding homogeneous solutions of the form above. We just have to be careful to remember that  $\underline{v}$  is an eigenvector with eigenvalue  $\lambda = -\omega^2$ , i.e.  $\omega = \sqrt{-\lambda}$ .

Note: In analogy with the scalar undamped oscillator DE

$$x''(t) + \omega_0^2 x = 0$$

where we could read off and check the solutions

$$\cos(\omega_0 t), \sin(\omega_0 t)$$

directly without going throught the characteristic polynomial, it is easy to check that

$$\cos(\omega t)\underline{v}, \sin(\omega t)\underline{v}$$

each solve the conserved energy mass spring system

$$\underline{x}^{\prime\prime}(t) = A \underline{x}$$

as long as

$$-\omega^2 \mathbf{v} = A \mathbf{v}$$
.

This leads to the

Solution space algorithm: Consider a very special case of a homogeneous system of linear differential equations,

$$\underline{x}^{\prime\prime}(t) = A \underline{x}$$

 $\underline{\boldsymbol{x}}^{\prime\prime}(t) = A\,\underline{\boldsymbol{x}}\ .$  If  $A_{n\times n}$  is a diagonalizable matrix and if all of its eigenvalues are negative, then for each eigenpair  $\left(\lambda_{j},\underline{\boldsymbol{v}}_{j}\right)$  there are two linearly independent solutions to  $\underline{\boldsymbol{x}}^{\prime\prime}(t) = A\,\underline{\boldsymbol{x}}$  given by

$$\mathbf{x}_{j}(t) = \cos(\omega_{j} t) \mathbf{\underline{y}}_{j}$$
  $\mathbf{\underline{y}}_{j}(t) = \sin(\omega_{j} t) \mathbf{\underline{y}}_{j}$ 

with

$$\omega_j = \sqrt{-\lambda_j}$$

 $\omega_j = \sqrt{-\lambda_j} \ .$  This procedure constructs 2 *n* independent solutions to the system  $\underline{x}''(t) = A \underline{x}$ , i.e. a basis for the solution space.

Remark: What's amazing is that the fact that if the system is conservative, the acceleration matrix will always be diagonalizable, and all of its eigenvalues will be non-positive. In fact, if the system is tethered to at least one wall (as in the first two diagrams on page 1), all of the eigenvalues will be strictly negative, and the algorithm above will always yield a basis for the solution space. (If the system is not tethered and is free to move as a train, like the third diagram on page 1, then  $\lambda = 0$  will be one of the eigenvalues, and will yield the constant velocity and displacement contribution to the solution space,  $(c_1 + c_2 t)\underline{v}$ , where  $\underline{v}$  is the corresponding eigenvector. Together with the solutions from strictly negative eigenvalues this will still lead to the general homogeneous solution.)

Exercise 2) Consider the special case of the configuration on page one for which  $m_1 = m_2 = m$  and  $k_1 = k_2 = k_3 = k$ . In this case, the equation for the vector of the two mass accelerations reduces to

$$\begin{bmatrix} x_1''(t) \\ x_2''(t) \end{bmatrix} = \begin{bmatrix} -\frac{2k}{m} & \frac{k}{m} \\ \frac{k}{m} & -\frac{2k}{m} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$
$$= \frac{k}{m} \begin{bmatrix} -2 & 1 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}.$$

a) Find the eigendata for the matrix

$$\left[\begin{array}{cc} -2 & 1 \\ 1 & -2 \end{array}\right].$$

- b) Deduce the eigendata for the acceleration matrix A which is  $\frac{k}{m}$  times this matrix.
- c) Find the 4- dimensional solution space to this two-mass, three-spring system.

solution The general solution is a superposition of two "fundamental modes". In the slower mode both masses oscillate "in phase", with equal amplitudes, and with angular frequency  $\omega_1 = \sqrt{\frac{k}{m}}$ . In the faster mode, both masses oscillate "out of phase" with equal amplitudes, and with angular frequency

 $\omega_2 = \sqrt{\frac{3 k}{m}}$ . The general solution can be written as

$$\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = C_1 \cos\left(\omega_1 t - \alpha_1\right) \begin{bmatrix} 1 \\ 1 \end{bmatrix} + C_2 \cos\left(\omega_2 t - \alpha_2\right) \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$
 
$$= \left(c_1 \cos\left(\omega_1 t\right) + c_2 \sin\left(\omega_1 t\right)\right) \begin{bmatrix} 1 \\ 1 \end{bmatrix} + \left(c_3 \cos\left(\omega_2 t\right) + c_4 \sin\left(\omega_2 t\right)\right) \begin{bmatrix} 1 \\ -1 \end{bmatrix}.$$

<u>Exercise 3</u>) Show that the general solution above lets you uniquely solve each IVP uniquely. This should reinforce the idea that the solution space to these two second order linear homgeneous DE's is <u>four</u> dimensional.

$$\begin{bmatrix} x_1''(t) \\ x_2''(t) \end{bmatrix} = \begin{bmatrix} -\frac{2k}{m} & \frac{k}{m} \\ \frac{k}{m} & -\frac{2k}{m} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$
$$x_1(0) = a_1, \quad x_1'(0) = a_2$$
$$x_2(0) = b_1, \quad x_2'(0) = b_2$$

<u>Experiment:</u> Although we won't have time in class to measure the spring constants, I've measure them earlier. We can predict the numerical values for the two fundamental modes of the vertical mass-spring configuration corresponding to <u>Exercise 2</u>, and then check our predictions like we did for the single mass-spring configuration, I have brought along a demonstration so that we can see these two vibrations.

> Digits := 5:  

$$k := \frac{.05 \cdot 9.806}{.153}$$
;  
 $\omega l := \sqrt{\frac{k}{.05}}$ ;  $Tl := evalf\left(\frac{2 \cdot \pi}{\omega l}\right)$ ;  
 $\omega 2 := \sqrt{3.0} \cdot \omega l$ ;  $T2 := evalf\left(\frac{2 \cdot \pi}{\omega 2}\right)$ ;  
 $k := 3.2046$   
 $\omega l := 8.0057$   
 $T1 := 0.78483$   
 $\omega 2 := 13.867$   
 $T2 := 0.45311$  (1)

Exercise 4) Consider a train with two cars connected by a spring:

<u>4a)</u> Verify that the linear system of DEs that governs the dynamics of this configuration (it's actually a special case of what we did before, with two of the spring constants equal to zero) is

$$x_1'' = \frac{k}{m_1} \left( x_2 - x_1 \right)$$

$$x_2'' = -\frac{k}{m_2} (x_2 - x_1)$$

<u>4b</u>). Use the eigenvalues and eigenvectors computed below to find the general solution. For  $\lambda = 0$  and its corresponding eigenvector  $\underline{v}$  verify that you get two solutions

$$\underline{x}(t) = \underline{v} \text{ and } \underline{x}(t) = t\underline{v},$$

rather than the expected  $\cos(\omega t)\underline{v}$ ,  $\sin(\omega t)\underline{v}$ . Interpret these solutions in terms of train motions. You will use these ideas in some of your homework problems and in your lab exercise about molecular vibrations.

$$= Eigenvectors \left( \begin{bmatrix} -\frac{k}{m_1} & \frac{k}{m_1} \\ \frac{k}{m_2} & -\frac{k}{m_2} \end{bmatrix} \right);$$

$$= \begin{bmatrix} 0 \\ -\frac{k(m_1 + m_2)}{m_2 m_1} \\ 1 \end{bmatrix}, \begin{bmatrix} 1 & -\frac{m_2}{m_1} \\ 1 & 1 \end{bmatrix}$$

$$(2)$$

Math 2250-004 Tues Dec 6

7.4 Forced mass-spring systems

<u>Warm up exercise</u>: Here are two systems of differential equations, and the eigendata is as shown. The first order system could arise from an input-output model, and the second one could arise from an undamped two mass, three spring model. Write down the general solution to each system.

<u>1a)</u>

$$\begin{bmatrix} x_1' \\ x_2' \end{bmatrix} = \begin{bmatrix} -3 & 4 \\ 1 & -3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

<u>1b</u>)

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} -3 & 4 \\ 1 & -3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

eigendata: For the matrix

$$\left[\begin{array}{cc} -3 & 4 \\ 1 & -3 \end{array}\right]$$

for the eigenvalue  $\lambda = -5$ ,  $\underline{\mathbf{y}} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}^T$  is an eigenvector; for the eigenvalue  $\lambda = -1$ ,  $\underline{\mathbf{y}} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}^T$  is an eigenvector

Forced oscillations (still undamped):

$$M\underline{x}''(t) = K\underline{x} + \underline{F}(t)$$
  
 $\Rightarrow \underline{x}''(t) = A\underline{x} + M^{-1}\underline{F}(t)$ .

If the forcing is sinusoidal,

$$M \underline{x}''(t) = K \underline{x} + \cos(\omega t) \underline{G}_{0}$$
  
$$\Rightarrow \underline{x}''(t) = A \underline{x} + \cos(\omega t) \underline{F}_{0}$$

with 
$$\underline{F}_0 = M^{-1}\underline{G}_0$$
.

From the fundamental theorem for linear transformations we know that the general solution to this inhomogeneous linear problem is of the form

$$\underline{\mathbf{x}}(t) = \underline{\mathbf{x}}_{P}(t) + \underline{\mathbf{x}}_{H}(t) ,$$

and we've been discussing how to find the homogeneous solutions  $\underline{\mathbf{x}}_H(t)$  .

As long as the driving frequency  $\omega$  is NOT one of the natural frequencies, we don't expect resonance; the method of undetermined coefficients predicts there should be a particular solution of the form

$$\underline{\mathbf{x}}_{p}(t) = \cos(\omega t) \,\underline{\mathbf{c}}$$

where the vector  $\underline{c}$  is what we need to find.

Exercise 1) Substitute the guess  $\underline{x}_p(t) = \cos(\omega t) \underline{c}$  into the DE system

$$\underline{x}^{\prime\prime}(t) = A\underline{x} + \cos(\omega t)\underline{F}_0$$

to find a matrix algebra formula for  $\underline{c} = \underline{c}(\omega)$ . Notice that this formula makes sense precisely when  $\omega$  is NOT one of the natural frequencies of the system.

Solution:

$$\underline{\boldsymbol{c}}(\boldsymbol{\omega}) = -\left(\boldsymbol{A} + \boldsymbol{\omega}^2 \boldsymbol{I}\right)^{-1} \underline{\boldsymbol{F}}_0.$$

Note, matrix inverse exists precisely if  $-\omega^2$  is not an eigenvalue.

Exercise 2) Continuing with the configuration from page 1 of Monday's notes, but now for an inhomogeneous forced problem, let k = m, and force the second mass sinusoidally:

$$\begin{bmatrix} x_1''(t) \\ x_2''(t) \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \cos(\omega t) \begin{bmatrix} 0 \\ 3 \end{bmatrix}$$

We know from previous work that the natural frequencies are  $\omega_1 = 1$ ,  $\omega_2 = \sqrt{3}$  and that

$$\underline{\boldsymbol{x}}_{H}(t) = C_{1} \cos\left(t - \alpha_{1}\right) \begin{bmatrix} 1 \\ 1 \end{bmatrix} + C_{2} \cos\left(\sqrt{3}t - \alpha_{2}\right) \begin{bmatrix} 1 \\ -1 \end{bmatrix}.$$

Find the formula for  $\underline{x}_P(t)$ , as on the preceding page. Notice that this steady periodic solution blows up as  $\omega \to 1$  or  $\omega \to \sqrt{3}$ . (If we don't have time to work this by hand, we may skip directly to the technology check on the next page. But since we have quick formulas for inverses of 2 by 2 matrices, this is definitely a computation we could do by hand.)

<u>Solution</u>: As long as  $\omega \neq 1, \sqrt{3}$ , the general solution  $\underline{x} = \underline{x}_P + \underline{x}_H$  is given by

$$\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = \cos(\omega t) \begin{bmatrix} \frac{3}{(\omega^2 - 1)(\omega^2 - 3)} \\ \frac{6 - 3\omega^2}{(\omega^2 - 1)(\omega^2 - 3)} \end{bmatrix} + C_1 \cos(t - \alpha_1) \begin{bmatrix} 1 \\ 1 \end{bmatrix} + C_2 \cos(\sqrt{3}t - \alpha_2) \begin{bmatrix} 1 \\ -1 \end{bmatrix}.$$

Interpretation as far as inferred practical resonance for slightly damped problems: If there was even a small amount of damping, the homogeneous solution would actually be transient (it would be exponentially decaying and oscillating - underdamped). There would still be a sinusoidal particular solution, which would have a formula close to our particular solution, the first term above, as long as  $\omega \neq 1, \sqrt{3}$ . (There would also be a relatively smaller  $\sin(\omega t)\underline{d}$  term as well.) So we can infer the practical resonance behavior for different  $\omega$  values with slight damping, by looking at the size of the  $\underline{c}(\omega)$  term for the undamped problem....see next page for visualizations.

= `practical resonance as function of forcing period` ;

practical resonance as function of forcing period

There are strong connections between our discussion here and the modeling of how earthquakes can shake buildings:

· Transverse oscillations! (i.e. directions I to the mass-spring configuration)

By linearization, a good model would be

$$\begin{aligned} & m_1 \times_1'' = -K_1 \times_1 + K_2 (x_2 - x_1) &= -(K_1 + K_2) \times_1 + K_2 \times_2 \\ & m_2 \times_2'' = K_2 (x_1 - x_1) - K_3 \times_2 = K_2 \times_1 - (K_2 + K_3) \times_2 \end{aligned}$$

where Ki, K2 K3 are positive constants as before

-> but in general not the Itooke's constants, because to first order the springs are not being stretched beyond their equilibrium lengths in this model

2nd order linear DE's; forcing and resonance will also be analogous to longitudinal vibrations, but probably with different resonant frequencies & & fundamental modes.

As it turns out, for our physics lab springs, the modes and frequencies are almost identical:

it turns out, for our physics lab springs, the modes and frequencies are almost identical:

$$\begin{bmatrix}
\text{force picture, e.g.} \\
\ell_1 \\
\ell_2
\end{bmatrix}$$

$$\begin{bmatrix}
\text{horiz force from top spring on mass 1} \\
= -T_1 \sin \theta_1 = -T_1 \frac{x_1}{\sqrt{\ell_1^2 + x_1^2}} & \chi - T_1 \frac{x_1}{\ell_1} = -\frac{T_1}{\ell_1} \\
\text{So } K_1 = \frac{T_1}{\ell_1}
\end{bmatrix}$$
So  $K_1 = \frac{T_1}{\ell_1}$ 

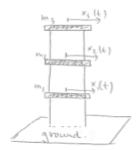

similarly, K2= T2, K3= T3

for our physics demo springs, equilibrium length \$0, very Hookesian so 
$$T \cong kl$$
;  $\underline{L} \approx k$ , so actually almost recover same fundamental modes!

• An interesting shake-table demonstration:

## http://www.youtube.com/watch?v=M x2jOKAhZM

Below is a discussion of how to model the unforced "three-story" building shown shaking in the video above, from which we can see which modes will be excited. There is also a "two-story" building model in the video, and its matrix and eigendata follow. Here's a schematic of the three-story building:

For the unforced (homogeneous) problem, the accelerations of the three massive floors (the top one is the roof) above ground and of mass m, are given by

$$\begin{bmatrix} x_1''(t) \\ x_2''(t) \\ x_3''(t) \end{bmatrix} = \frac{k}{m} \begin{bmatrix} -2 & 1 & 0 \\ 1 & -2 & 1 \\ 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \\ x_3(t) \end{bmatrix}.$$

Note the -1 value in the last diagonal entry of the matrix. This is because  $x_3(t)$  is measuring displacements for the top floor (roof), which has nothing above it. The "k" is just the linearization proportionality factor, and depends on the tension in the walls, and the height between floors, etc, as discussed on the previous page.

Here is eigendata for the <u>unscaled matrix</u>  $\left(\frac{k}{m} = 1\right)$ . For the scaled matrix you'd have the same eigenvectors, but the eigenvalues would all be multiplied by the scaling factor  $\frac{k}{m}$  and the natural

frequencies would all be scaled by  $\sqrt{\frac{k}{m}}$ . Symmetric matrices like ours (i.e matrix equals its transpose) are always diagonalizable with real eigenvalues and eigenvectors...and you can choose the eigenvectors to be mutually perpendicular. This is called the "Spectral Theorem for symmetric matrices" and is an important fact in many math and science applications...you can read about it here: <a href="http://en.wikipedia.org/wiki/Symmetric\_matrix">http://en.wikipedia.org/wiki/Symmetric\_matrix</a>.) If we tell Maple that our matrix is symmetric it will not confuse us with unsimplified numbers and vectors that may look complex rather than real.

$$A := \begin{bmatrix} -2.0 & 1 & 0 \\ 1 & -2 & 1 \\ 0 & 1 & -1 \end{bmatrix}$$
 (4)

omegas := map(sqrt, -lambdas); # natural angular frequencies

eigenvectors := map(evalf, evectors); # get digits down to 5

 $2 \cdot evalf(Pi)$ 

periods := map(f, omegas); #natural periods

Exercise 3) Interpret the data above, in terms of the natural modes for the shaking building. In the youtube video the first mode to appear is the slow and dangerous "sloshing mode", where all three floors oscillate in phase, with amplitude ratios 33:59:74 from the first to the third floor. What's the second mode that gets excited? The third mode? (They don't show the third mode in the video.)

**(6)** 

omegas :=  $\begin{bmatrix} 1.6180 \\ 0.61804 \end{bmatrix}$   $periods := \begin{bmatrix} 3.8834 \\ 10.166 \end{bmatrix}$   $eigenvectors := \begin{bmatrix} -0.85065 & -0.52573 \\ 0.52573 & -0.85065 \end{bmatrix}$ 

<u>Remark</u>) All of the ideas we've discussed in section 7.4 also apply to molecular vibrations. The eigendata in these cases is related to the "spectrum" of light frequencies that correspond to the natural fundamental modes for molecular vibrations.
