Math 2270-2
Final Exam
December 13, 2001

This exam is closed-book and closed-note. You may not use a calculator which is capable of doing linear algebra computations. In order to receive full or partial credit on any problem, you must show all of your work and **justify your conclusions**. There are 200 points possible, and the point values for each problem are indicated in the right-hand margin. Of course, this exam counts for 30% of your final grade even though it is scaled to 200 points. Good Luck!

1) Let

$$A := \begin{bmatrix} 1 & -2 & 0 & 2 \\ 2 & -4 & 1 & 3 \\ -1 & 2 & 1 & -3 \\ 0 & 0 & 1 & -1 \end{bmatrix}$$

Then $T(x) := Ax$ is a linear map from \mathbf{R}^4 to \mathbf{R}^4 . Here are the reduced row echelon forms of A and of the transpose of A :

$$\text{RREF}(A) := \begin{bmatrix} 1 & -2 & 0 & 2 \\ 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\text{RREF}(A^T) := \begin{bmatrix} 1 & 0 & -3 & -2 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

1a) Find a basis for the kernel of T .

(10 points)

1b) Find a basis for the image of T .

(5 points)

1c) Express the 4th column of A as a linear combination of the two non-zero rows in the reduced row echelon form of A transpose.

(5 points)

1d) For a subspace V of \mathbb{R}^n , define what is meant by the orthogonal complement to V .

(5 points)

1e) For the matrix A on page 1, find a basis for the orthogonal complement to the kernel of A . What do we usually call this subspace, which is one of the four fundamental subspaces associated to the matrix? (5 points)

1f) For our matrix A on page 1, find a basis for the orthogonal complement to the image of A . What is another name for this subspace? (10 points)

2a) Exhibit the rotation matrix which rotates vectors in \mathbb{R}^2 by an angle of α radians in the counter-clockwise direction.

(5 points)

2b) Verify that the product of an α -rotation matrix with a β -rotation matrix is an $(\alpha+\beta)$ -rotation matrix.

(7 points)

2c) Use Euler's formula to expand both sides of the identity

$$e^{i\alpha} e^{i\beta} = e^{i(\alpha+\beta)}$$

and verify that (as in 2b) this identity is equivalent to the addition angle formulas for cos and sin.

(8 points)

3) Let V be the vector space of polynomials in t of degree at most 1. Let $T:V \rightarrow V$ be defined by

$$T(f) := 3D(f) - 2f$$

where D stands for t -derivative.

3a) Show that T is linear.

(5 points)

3b) Let

$$\beta = \{1, t\}$$

be a basis for V . Find the matrix B for T with respect to this basis.

(10 points)

3c) Let

$$\Gamma = \{1+t, 1-t\}$$

be a different basis for V . Find the matrix S which converts Gamma-coordinates to beta coordinates. In other words, S times the Gamma-coordinates of a vector yields the beta-coordinates.

(5 points)

3d) Use the matrix S from part 3c and its inverse, together with the matrix B from part 3b, in order to find the matrix G for T with respect to the basis Gamma. (Or, for only 5 points, find this matrix another way.)

(10 points)

4) Let

$$A := \begin{bmatrix} 1 & 1 \\ -1 & 0 \\ 1 & 1 \\ -1 & 0 \end{bmatrix}$$
$$b := \begin{bmatrix} 1 \\ 2 \\ 3 \\ 0 \end{bmatrix}$$

4a) If you have studied carefully you know how to find the least squares solution to $Ax=b$, by solving the system

$$A^T A x = A^T b$$

Carry out his procedure to find the least squares problem for A and b as above.

(5 points)

4b) The least squares solution is the vector x so that Ax equals the projection of b onto the image of A . Use this characterization to explain the derivation of the displayed formula in part 4a.

(5 points)

4c) Find an orthonormal basis for the column space (=image) of A .

(10 points)

4d) Find the projection of b onto the column space of A , using your basis from 4b.

(5 points)

4e) Verify that the projection of b which you found in 4c does indeed equal Ax , where x is the least squares solution you found in 4a.

(5 points)

5) This is a discrete dynamical system story problem: Company "B" invents a new, neat internet application, which can be downloaded from their company page for a cost of \$10.00. Company "M" reverse engineers the product, and begins including the application as a free part of their dominant browser package. Let $x(t)$ represent the fraction of computers using B's application or no application at all, and let $y(t)$ represent the fraction of computers using M's version. Suppose that initially, $x(0)=1$, $y(0)=0$.

Suppose that the following transition equation describes how these fractions change month by month:

$$\begin{bmatrix} x(t+1) \\ y(t+1) \end{bmatrix} = \begin{bmatrix} .8 & .05 \\ .2 & .95 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$
$$\begin{bmatrix} x(0) \\ y(0) \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

5a) Explain the meaning of the transition equations above: how do customers change applications from month to month? A diagram may help.

(5 points)

5b) Find the eigenvalues and eigenvectors for the transition matrix above. Hint: this is a regular transition matrix so $\lambda=1$ will be an eigenvalue. This should help you factor the characteristic polynomial.

(20 points)

5c) Using the eigenvalues and eigenvectors from part 5b find a closed form expression for

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

(5 points)

5d) What fractions will $x(t)$ and $y(t)$ be close to 12 months later?

(5 points)

6a) Explain the procedure which allows one to convert a general quadratic equation in n-variables

$$x^T A x + B x + c = 0$$

into one without any "cross terms". Be precise in explaining the change of variables, and the justification for why such a change of variables exists.

(5 points)

6b) Apply the procedure from part (4a) to put the conic section (this is a curve in R^2)

$$5x^2 + 6xy - 3y^2 = 24$$

into standard form. Identify the conic section and sketch it in the x-y plane (use the next page), showing the rotated axes.

(20 points)

7) True-False. Four points each (2 points for answer, two points for justification.)

(20 points)

7i) Let A be a nonsingular n by n matrix. Then the equation $Ax=Ay$ implies that $x=y$.

7ii) In the discrete dynamical system problem #5 above, if the initial customer distribution had included a positive fraction who already used the company M software (so that $y(0)>0$), then the limiting market share for company M would have been even greater.

7iii) If A and B are symmetric (square) matrices (of the same size) then so is their product AB .

7iv) Let A be a rectangular matrix whose columns are orthonormal. Then

$$A^T A = I$$

where I is the identity matrix.

7v) There exists a matrix with three rows and four columns which has the property that the columns are orthonormal.
