## WHY ROW REPLACEMENT DOESN'T CHANGE THE SOLUTION SET

A couple of you have asked about a rigorous explanation of why this is true. Here's how I would explain it.

Suppose we are given a system of linear equations in $n$ variables and $m$ equations,

$$
\begin{aligned}
& a_{11} x_{1}+\ldots+a_{1 n} x_{n}=b_{1} \\
& a_{21} x_{1}+\ldots+a_{2 n} x_{n}=b_{2} \\
& \ldots
\end{aligned}
$$

For shorthand, lets call this system of equations $S$. We want to show that it has the same solution as the system obtained by adding $c$ times the $i$ th row of $S$ to the $j$ th row of $S$. ( $i$ and $j$ are arbitrary integers between 1 and $m$ ). We call this new, row-replaced system $S^{\prime}$.

There are two things to show. Every solution of $S$ is a solution of $S^{\prime} A N D$ every solution of $S^{\prime}$ is a solution of $S$.

To start with, let $t=\left(t_{1}, \ldots, t_{n}\right)$ be a solution of $S$. We want to show it is also a solution of $S^{\prime}$. Note that

$$
\begin{equation*}
a_{k 1} t_{1}+\ldots+a_{k n} t_{n}=b_{k} \tag{1}
\end{equation*}
$$

holds for every value of $k$, and so it is easy to see that $t$ is a solution for every equation of $S^{\prime}$ (except possibly the $j$ th one, ie. the modified one). The $j$ th equation of $S^{\prime}$ is

$$
c\left(a_{i 1} x_{1}+\ldots+a_{i n} x_{n}\right)+a_{j 1} x_{1}+\ldots+a_{j n} x_{n}=c b_{i}+b_{j} .
$$

However, if we substitute the $t$ 's into the $x$ 's, using (1), we get that

$$
c b_{i}+b_{j}=c b_{i}+b_{j},
$$

which is certainly true. Therefore, every solution of $S$ is also a solution of $S^{\prime}$.
To show the converse (that is, to show that every solution of $S^{\prime}$ is a solution of $S$ ) we note the following fact. One can do a single row replacement operation to $S^{\prime}$ to re-obtain $S$ (add $-c$ times row $i$ to row $j$ ). Thus we can perform the same argument as above (with the roles of $S$ and $S^{\prime}$ reversed) and see that every solution of $S^{\prime}$ is also a solution of $S$.
