Conclusions

- 1. Sea ice is a fascinating multiscale composite with structure similar to many other natural and man-made materials.
- 2. Mathematical methods developed for sea ice advance the theory of composites and other areas of science and engineering.
- 3. Homogenization and statistical physics help *link scales in sea ice* and composites; provide rigorous methods for finding effective behavior; advance sea ice representations in climate models.
- 4. Fluid flow through sea ice mediates melt pond evolution and many processes important to climate change and polar ecosystems.
- 5. Field experiments are essential to developing relevant mathematics.
- 6. Our research is helping to improve projections of climate change, the fate of Earth's sea ice packs, and the ecosystems they support.

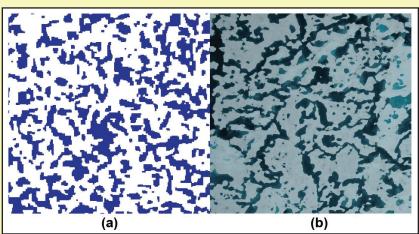

Figure 3. Comparison of real Arctic melt ponds with metastable equilibria in our melt pond Ising model. 3a. Ising model simulation. 3b. Real melt pond photo. Figure 3a courtesy of Yiping Ma, 3b courtesy of Donald Perovich.

Vast labyrinthine ponds on the surface of melting Arctic sea ice are key players in the polar climate system and upper ocean ecology. Researchers have adapted the Ising model, which was originally developed to understand magnetic materials, to study the geometry of meltwater's distribution over the sea ice surface. In an article on page 5, Kenneth Golden, Yiping Ma, Courtenay Strong, and Ivan Sudakov explore model predictions.

Controlling Invasive Populations in Rivers

By Yu Jin and Suzanne Lenhart

 $\Gamma^{
m low}$ regimes can change significantly over time and space and strongly impact all levels of river biodiversity, from the individual to the ecosystem. Invasive species in rivers-such as bighead and silver carp, as well as quagga and zebra mussels—continue to cause damage. Management of these species may include targeted adjustment of flow rates in rivers, based on recent research that examines the effects of river morphology and water flow on rivers' ecological statuses. While many previous methodologies rely on habitat suitability models or oversimplification of the hydrodynamics, few studies have focused on the integration of ecological dynamics into water flow assessments.

Earlier work yielded a hybrid modeling approach that directly links river hydrology with stream population models [3]. The hybrid model's hydrodynamic component is based on the water depth in a gradually varying river structure. The model derives the steady advective flow from this structure and relates it to flow features like water discharge, depth, velocity, cross-

sectional area, bottom roughness, bottom slope, and gravitational acceleration. This approach facilitates both theoretical understanding and the generation of quantitative predictions, thus providing a way for scientists to analyze the effects of river fluctuations on population processes.

When a population spreads longitudinally in a one-dimensional (1D) river with spatial heterogeneities in habitat and temporal fluctuations in discharge, the resulting hydrodynamic population model is

$$\begin{split} N_t &= -A_t(x,t) \frac{N}{A(x,t)} + \\ &\frac{1}{A(x,t)} \Big(D(x,t) A(x,t) N_x \Big)_x - \\ &\frac{Q(t)}{A(x,t)} N_x + r N \bigg(1 - \frac{N}{K} \bigg) \\ N(0,t) &= 0 & \text{on } (0,T), x = 0, \\ N_x(L,t) &= 0 & \text{on } (0,T), x = L, \\ N(x,0) &= N_0(x) & \text{on } (0,L), t = 0 \end{split}$$

See Invasive Populations on page 4

Modeling Resource Demands and Constraints for COVID-19 Intervention Strategies

By Erin C.S. Acquesta, Walt Beyeler, Pat Finley, Katherine Klise, Monear Makvandi, and Emma Stanislawski

As the world desperately attempts to control the spread of COVID-19, the need for a model that accounts for realistic trade-offs between time, resources, and corresponding epidemiological implications is apparent. Some early mathematical models of the outbreak compared trade-offs for non-pharmaceutical interventions [3], while others derived the necessary level of test coverage for case-based interventions [4] and demonstrated the value of prioritized testing for close contacts [7].

Isolated analyses provide valuable insights, but real-world intervention strategies are interconnected. Contact tracing is the lynchpin of infection control [6] and forms the basis of prioritized testing. Therefore, quantifying the effectiveness of contact tracing is crucial to understanding the real-life implications of disease control strategies.

Contact Tracing Demands

Contact tracers are skilled, culturally competent interviewers who apply their knowledge of disease and risk factors when notifying people who have come into contact with COVID-19-infected individuals. They also continue to monitor the situation after case investigations [1].

Case investigation consists of four steps:

- 1. Identify and notify cases
- 2. Interview cases
- 3. Locate and notify contacts
- 4. Monitor contacts.

Most health departments are implementing case investigation, contact identification, and quarantine to disrupt COVID-19 transmission. The timeliness of contact tracing is constrained by the length of the infectious period, the turn-around time for testing and result reporting, and the ability to successfully reach and interview patients and their contacts. The European Centre for Disease Prevention and Control approximates that contact tracers spend one to two hours conducting an interview [2]. Estimates regarding the timelines of other steps are limited to subject matter expert elicitation and can vary based on cases' access to phone service or willingness to participate in interviews.

Bounded Exponential

The fundamental structure of our model follows traditional susceptible-exposed-infected-recovered (SEIR) compartmental modeling [5]. We add an asymptomatic population A, a hospitalized population H, and disease-related deaths D, as well as corresponding quarantine states. We define the states $\{S_i, E_i, A_i, I_i, H, R, D\}_{i=0,1}$ for our compartments, such that i=0 and i=1

correspond to unquarantined and quarantined respectively. Rather than focus on the dynamics that are associated with the state transition diagram in Figure 1, we introduce a formulation for the real-time demands on contact tracers' time as a function of infection prevalence, while also respecting constraints on resources.

When the work that is required to investigate new cases and monitor existing contacts exceeds available resources, a backlog develops. To simulate this backlog, we introduce a new compartment ${\cal C}$ for tracking the dynamic states of cases:

$$\frac{dC}{dt} \!=\! [\mathit{flow}_{\scriptscriptstyle in}] \!-\! [\mathit{flow}_{\scriptscriptstyle out}].$$

Flow into the backlog compartment, represented by $[flow_{in}]$, reflects case identification that is associated with the following transitions in the model:

- The population that was missed by the non-pharmaceutical interventions that require hospitalization: $\tau_{IH}(t)I_0(t) \rightarrow H(t)$.

Here, $q_{x*}(t)$ defines the time-dependent rate of random testing, $q_{t*}(t)$ signifies the time-dependent rate of testing that is triggered by contact tracing, and $\tau_{\rm IH}$ is the inverse of the expected amount of time for which an infected individual is symptomatic before hospitalization. These terms collectively provide the simulated number of newly-identified positive COVID-19 cases. However, we also need the average number of contacts per case. We thus define function $\mathcal{K}(\kappa, T_{_S}, \phi_{_\kappa})$ that depends on the average number of contacts a day (κ) , the average number of days for which an individual is infectious before going into isolation (T_s) , and the likelihood that the individual

Fire endangers Hobart's ice ship

BY DAVID CARRIGG

AN engine-room fire has left the Hobart-based Antarctic research ship Aurora Australia without power in dangerous sea ice off the Antarctic coast.

None of the 79 people on board was injured in the blaze, which broke out early yesterday morning while the ship was in deep water 185km off the coast.

The extent of the damage is not known.

Australian Antarctic Division director Rex Moncur said the fire was extinguished by flooding the engine room with an inert gas.

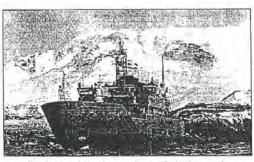

The gas had to be cleared before crew wearing breathing apparatus could enter and assess the situation.

He said it could be some time before the extent of damage was

The 25 crew and 54 expeditioners, mostly from Hobart, would wear thermal clothing and stay below decks to keep

"There is always a risk of becoming ice-bound in these waters at this time of the year rut at this stage we don't expect to launch a rescue mission from Hobart," Mr Moncur said.

The ship was in regular radio contact with the Antarctic Div-

ision's Hobart office.

He expected the expeditioners and crew to abandon the pioneering winter voyage and return the ship to Hobart for repairs in about a week.

The Antarctic Division, which hires the ship from P&O Australia, would not be hiring another vessel for the expedition.

"It's a pretty specialist vessel so you couldn't get the sort of research capability that this ship has got readily available," Mr Moncur said.

"We hope the next voyage can still proceed on schedule, which is early September."

The Aurora Australis is owned by P&O Australia and charted by the Antarctic Division for about \$11 million

Australia managing director Richard Hein said yesterday the company was assessing the situation and a number of rescue options were being

It was too early to say whether P&O would be liable for the cost of the aborted

The vessel left Hobart last Wednesday for a seven-week voyage mainly to study a polyn-ya, an area where savage winds break up the sea ice and cause heavy, salt-laden water to sink to the bottom.

The ship was nearing the polynya when the fire broke out.

Australia Hobart Casev Antarctica

Oceanographers believe a closer study of the phenomenon will lead to a better understanding of climate change.

CSIRO Marine Research oceanographer Steve Rintoul said the dense bottom water, created only in a few places in Antarctica and to a lesser extent in the North Atlantic, was critical to the chemistry and biology of the world's oceans.

Antarctic voyage stopped

by fire HOBART: An engine room fire has disabled the Austra: lian icebreaker Aurora Australis in sea ice, deep in Antarctic

Australian Antarctic Division director Rex Moneur said there were no injuries and the ship was not in danger after Tuesday night's fire.

But Mr Moncur said he expected Aurora Australis would have to abandon its ploneering mid-winter voyage to the edge of the Antarctic continent to return to Hobart for repairs.

The fire had been extinguished and the engines were turned off, leaving the ship in sea ice about 100 nautical miles from the Antarctic coast, he said. The weather was good.

Crew had to wear breathing apparatus to enter the engine room and it was likely to be 24 hours before the damage could be fully assessed.

The Aurora, with 54 expeditioners and 25 crew, left Hobart last Wednesday for a seven-week voyage which was to have focused on a polynya, an area where savage winds break up the sea ice and cause beavy, salt-laden water to sink to the bottom.

Mr Moncur said, the cause of the fire was not yet known.
