If  $f$  is continuous on a closed interval  $[a, b]$  and differentiable on its interior  $(a, b)$ , then there is at least one point  $c$  in  $(a, b)$  such that

$$\frac{f(b) - f(a)}{b - a} = f'(c)$$

or equivalently

$$f(b) - f(a) = f'(c)(b - a)$$

Let  $f$  be twice differentiable on an open interval containing  $c$ , and suppose  $f'(c) = 0$ .

1. If  $f''(c) < 0$ , then  $f$  has a **local maximum** at  $c$ .
2. If  $f''(c) > 0$ , then  $f$  has a **local minimum** at  $c$ .
3. If  $f''(c) = 0$ , then the test fails.
